React Todo App Component Architecture & Learning Outcomes

1. Component Architecture

Your app follows a component-based architecture, where the UI is split into reusable units.

Components: -

App.js: Root component holding todos state, CRUD methods, and localStorage.

Todoform.js: Handles adding new todos using controlled input.

Todoitem.js: Displays each todo, allows editing, completion toggling, and deletion.

context/index.js: Creates and exports TodoContext, useTodo hook, and TodoProvider.

- **App.js** → The root component
  - Holds todos state and CRUD functions (addTodo, updateTodo, deleteTodo, toggleComplete)
  - Uses TodoProvider from context to share state/functions globally
  - Renders <Todoform /> and <Todoitem /> for each todo
  - Handles **localStorage** persistence
- **Todoform.js** → Controlled form component
  - Manages the input for a new todo
  - Calls addTodo from context when submitted
  - Resets the input after submission
- **Todoitem.js** → Single todo display & controls
  - Displays the todo text and checkbox
  - Allows toggling completion, editing, and deleting
  - Uses local state for editing mode
- **context/index.js** → Context provider
  - Creates a TodoContext
  - Exposes the useTodo hook
  - Makes todos and CRUD functions available without prop drilling

2. Learning Outcomes

Outcome 1: Understand React Component Architecture

- Components are separated by responsibility.
- Context API avoids prop drilling.

Outcome 2: Apply Best Practices for Component Design

- Single Responsibility Principle applied.
- State is lifted to App.js.
- LocalStorage ensures persistence.

Outcome 3: Develop Skills in Props Passing & Component Reuse

- Props are used in Todoitem for displaying data.
- Components are reusable in different UI contexts.

3. React Documentation References

- React Components: https://react.dev/learn/your-first-component

- Props: https://react.dev/learn/passing-props-to-a-component
- State & Hooks: https://react.dev/learn/state-a-components-memory
- Context API: https://react.dev/reference/react/useContext

4. CSS Styling Guides

- Use descriptive class names (e.g., .form-input, .form-btn).
- Avoid global CSS conflicts with prefixed class names.
- Consider CSS Modules for better scoping.

5. Code Explanation Summary

Data Flow:

App.js manages todos state and passes via TodoProvider.

Todoform and Todoitem access and update state using context.

State Management:

useState manages todos and form input.

useEffect syncs data with localStorage.

6. Example Repository Submission Include in submission:
